

Import Data Using Transform Maps (Spreadsheet)

2. Requirement Analysis

Functional and non-functional requirements for the Transform Map import project

Functional Requirements

The system should accept spreadsheet data, create or use an Import Set Table, allow creation of a Transform Map, map source fields to target fields, apply transformation logic where needed, run the import, and verify the resulting target records.

Data Requirements

The spreadsheet should contain clear column headings and valid records. Source fields may include identifiers, names, descriptions, dates, categories and other project-specific values. Duplicate or invalid records should be identified according to the chosen rules.

Non-Functional Requirements

The process should be simple to operate, reasonably efficient, maintain data accuracy, provide understandable error information and maintain consistency between source and target data.

Users and Roles

A project administrator or developer configures the import process. An authorized user can upload the spreadsheet and run the import. Reviewers verify the imported records.

Constraints

The source spreadsheet format, column names, data types, mandatory fields and target table structure must be compatible with the transformation design.

Project: Import Data Using Transform Maps (Spreadsheet)
