

Import Data Using Transform Maps (Spreadsheet)

3. Project Design Phase

Design of the spreadsheet-to-target-table import workflow

System Design

The project is designed as a sequence: Spreadsheet → Import Set → Import Set Table → Transform Map → Field Mapping/Transformation → Target Table → Validation.

Data Mapping Design

Each spreadsheet column is matched with the appropriate target field. For example, a source column such as Name can map to a target Name field, while a source Category column can be converted to the required target value before insertion.

Transformation Design

Transformation logic is used when source data does not directly match the target format. Examples include trimming spaces, converting text formats, setting default values, or translating source values into accepted target values.

Validation Design

The design includes checks for mandatory fields, duplicate records, invalid values, incorrect formats and records that fail transformation.

Error Handling

Failed records should be reviewed through import logs and error information. The source data can then be corrected and imported again.
